

1. Script Idea

I'm making a watch time calculator for the `example_webpage.html` page. It will go in the movie details section where the three French films are shown.

Basically users can check boxes next to the movies they want to watch and then click a button to see how long it will take to watch all of them. The script adds up the runtime for each selected movie and shows the total in hours and minutes.

This makes the search results more useful because people can actually plan how much time they need. Like if someone wants to have a movie night they can see if they have enough time for 2 or 3 movies.

2. Goals

The main goal is to make the movie results more interactive and helpful. Right now the page just shows the movies but doesn't really do anything.

What I want to achieve:

- Let users select multiple movies
- Calculate total watch time automatically
- Show results in an easy to read format (hours and minutes not just minutes)
- Update the page without reloading

This should make the site feel more like a real tool people would actually use instead of just a static page with information.

3. Task Breakdown

Step 1: Set up the movie data

Store each movie's name and runtime in variables. Like `movie1 = "Gemma Boveri"` and `runtime1 = 99 minutes`.

Step 2: Add HTML elements

Put checkboxes next to each movie in the table. Add a calculate button and a spot to show the results.

Step 3: Get user selections

When someone clicks the button, check which boxes are checked.

Step 4: Do the math

Add up the runtimes for the checked movies. Count how many movies they picked.

Step 5: Convert to hours and minutes

Divide total minutes by 60 to get hours. Use the remainder for minutes.

Step 6: Make the message

Put together a string that says how many movies and total time. Handle cases like if they pick 1 movie vs multiple.

Step 7: Show it on the page

Update the HTML element with the result message.

4. Flowchart

The flowchart shows the logic flow:

- Start when page loads
- Show the three movies with checkboxes
- Wait for user to select movies and click button
- Check if any movies are selected
 - If no: show error message "please select at least one movie"
 - If yes: continue
- Initialize variables (totalMinutes = 0, movieCount = 0)
- Loop through each checkbox
 - If checked: add that movie's runtime to total and increment count
 - If not checked: skip it
- After loop, calculate hours and minutes from total
- Build the display message
- Update the page with results
- Wait for user to recalculate if they want

The flowchart image shows this visually with the decision diamonds for yes/no choices and boxes for the different steps.

Variables I'll use:

Strings:

- movie titles ("Gemma Boverly", "Young & Beautiful", "Last Summer")
- result message that gets displayed

Numbers:

- movie runtimes (99, 95, 104 minutes)
- totalMinutes (sum of selected movies)
- movieCount (how many they picked)
- hours and minutes (converted time)

Calculations:

- Addition: add up the runtimes
- Division: totalMinutes / 60 to get hours
- Modulo: totalMinutes % 60 to get remaining minutes

Example outputs:

- All 3 movies: "You selected 3 movies. Total Watch Time: 4 hours and 58 minutes"
- 2 movies: "You selected 2 movies. Total Watch Time: 3 hours and 14 minutes"
- None: "Please select at least one movie"
