

1. Code Segments to Modularize

Right now my `calculateWatchTime()` function does everything - it checks which movies are selected, adds up the runtimes, converts minutes to hours, and displays the result. That's too much in one function.

I'm going to break it into smaller pieces:

`formatTime(totalMinutes)` - converts minutes to "2 hours and 30 minutes" format

Parameters: `totalMinutes` (number)

Returns: formatted string

`validateSelection(checkbox1, checkbox2, checkbox3)` - checks if any movie is selected

Parameters: three checkbox elements

Returns: true or false

`addRuntimes(runtime1, runtime2, runtime3, checked1, checked2, checked3)` - adds up selected runtimes

Parameters: three runtime numbers and three booleans for whether each is checked

Returns: total minutes (number)

`displayWelcome()` - shows welcome message when page loads

Parameters: none

Returns: nothing

2. Why Use Functions

Breaking big code into smaller functions makes it easier to read because each function does one clear thing. Right now if I want to change how time is displayed, I have to find that code inside a huge function. With `formatTime()`, I just update one small function.

Also if I want to reuse the time formatting somewhere else (like showing total watchlist time), I can just call `formatTime()` instead of copying all that code again.

Functions make debugging easier too. If there's a bug in the time conversion, I only need to check `formatTime()` instead of searching through everything.

3. New Functions

`displayWelcome()` - basic function with no parameters, just logs a welcome message to console when page loads. Makes the site feel more personal.

`formatTime(totalMinutes)` - takes minutes as a parameter and returns a readable string. Makes the calculator cleaner and I can use this anywhere I need to display time.

`validateSelection(checkbox1, checkbox2, checkbox3)` - takes checkboxes as parameters and returns true/false. Separates validation from calculation so the code is more organized.

These functions make the main `calculateWatchTime()` function way shorter and easier to understand because it just calls other functions to do the work instead of doing everything itself.
